

Section C: Analysis and Visualisation

This section examines medical care as one part of the broader Student Liveability Index. Medical expenses can contribute to students' overall living costs, while access to healthcare is another consideration when choosing where to live. These indicators should be considered alongside rent, safety, transport accessibility and amenities.

Figure 1. GP care: selected low- and high-median-cost SA3 areas

This horizontal bar chart compares median GP costs across selected SA3 areas. It makes differences between the listed areas easy to see and helps identify places with relatively higher or lower median GP costs. This is relevant to the project because GP costs may contribute to students' out-of-pocket living expenses. A horizontal bar chart is effective for comparing ranked categories, especially when area names are long. However, the chart only shows selected SA3 areas, not every suburb in Greater Sydney, and SA3 boundaries do not necessarily match individual suburbs. Therefore, it should not be treated as a complete suburb ranking.

Figure 2. Combined data: GP vs specialist care coverage by SES

This grouped bar chart compares the percentage of patients with GP costs and specialist costs across socioeconomic groups (SES). The chart suggests that the percentages differ between service types and across SES groups. A grouped bar chart is useful because readers can compare GP and specialist care within each group. It provides context about healthcare use or coverage, which is relevant to students' consideration of essential services. However, SES groups are not individual suburbs, and the percentages do not directly measure waiting times, service quality, distance to a clinic or the affordability of care for a particular student.

Overall interpretation and limitations

Together, the figures provide two complementary perspectives: the cost of GP care in selected areas and differences in GP and specialist care coverage across SES groups. They can inform the medical-care component of the Student Liveability Index, but they cannot independently identify the best suburb for a USYD student. The group should combine these findings with rent and other cost data, safety, public transport accessibility and amenities. Before drawing conclusions, the original dataset's definitions, time period, geographic units and missing values should also be checked.
